 . Network on which a
plurality of measurement instruments are connected is
generally composed of wires on which the measurement
instruments are connected with wiring jigs. Such
network is moved and stored by the use of a remote-
controlled tool such as a vehicle that carries the wiring
jigs. After the measurement instruments are connected
with the network, the measurement instruments are
remote-controlled to transmit and receive the signals
from the network. Patent Literature 1 describes a
monitoring apparatus that includes a monitoring region
defined in a room, a wireless communications device
including an antenna that is supported to be slidable
along an axis and wires, which are connected with a
plurality of measurement instruments, that are slidable
along the axis in the monitoring region, and a control
device that is connected with the wireless
communications device to be remote-controlled and to
control the wireless communications device. In the

monitoring apparatus, each of the measurement instruments is set to be capable of transmitting and receiving the signals by the use of the wireless communications device. Further, the antenna is slid along the axis in accordance with the movement of the measurement instruments, and the wireless communications device is controlled to be slidable along the axis based on the information from the control device to adjust the position of the antenna with respect to the room.

Treatment of vestibular schwannomas: analysis of 413 surgically treated cases. The significance of microsurgical exploration in the management of vestibular schwannomas is still controversial. 413 patients underwent exploration over a 30 year period. The surgical approach to these tumors depended on their size, location, and the suitability of the facial nerve for anastomosis. The recurrence rate was 8.5%. Adjuvant radiation therapy (ERT) was used in cases not suitable for conventional surgery. Bilateral ear operations were performed more frequently than unilateral ones. Irradiation of the internal auditory canal was used more often in small tumors

WWW.DANISCOOS.COM Control units for use in motors, e.g. an electric motor, and/or other systems, are configured to be controlled by a microcontroller, such as a digital signal processor (“DSP”), to operate in one or more different modes. Control units in the form of controllers such as PID controllers are typically electronically configured for two types of control applications, on/off mode and proportional mode. Controller manufacturers typically define proprietary control system architectures and software programs to enable the units to operate in these modes. The operators typically download the software program on to a controller at the time of system configuration to achieve the system mode or modes to be used for the given application, e.g., on/off or proportional mode. In some applications, it would be advantageous to have the ability to change the settings of a control unit, e.g., a DSP, in real time, for the purposes of reacting to changing circumstances of the control system. For example, the software configured for a particular control system may be set to operate in an on/off mode in order to provide a “reset” function for a control system. However, it may be desirable to operate the control system in a proportional mode, as may be indicated by the changing circumstances, for example, a relatively fast change in the duty cycle of a pulse width

modulation (PWM) signal.
